This version: January 30, 1998

When we look at the best approximation error, the most conspicuous feature is equioscillation.

From well known exactly solvable minimax approximation problems, let us try

$$e^{-t} - \frac{P_n(t)}{Q_n(t)} = (-1)^n E_n \cos((2n+1)\theta_n(t))$$

and we look where $\theta_n(t) = \pi/2$ and $\pi/3$,

Conjecture (which we hope to prove some day!)

$$\theta_n((n + 1/2)u) \rightarrow_{n \rightarrow \infty} \theta(u). \quad (1)$$

$u = t/(n + 1/2)$	$\theta_4(t)/\pi$	$\theta_5(t)/\pi$	$\theta_6(t)/\pi$
